AWS Certificate Manager (ACM) — Important Interview Questions & Answers

1.What is AWS Certificate Manager (ACM)?
AWS Certificate Manager is a service used to create, manage, and renew SSL/TLS certificates.
These certificates are used to secure applications and websites with HTTPS.
Simple ga gurthupettuko:
ACM ante website ki HTTPS security kosam SSL/TLS certificate manage chese service.
Eng: ACM is used to manage SSL/TLS certificates for secure HTTPS connections.

2.Why do we use ACM?
We use ACM to secure websites and applications using HTTPS.
It also helps us manage and automatically renew supported certificates.
Simple ga gurthupettuko:
Website ni HTTPS tho secure cheyyadaniki ACM use chestham.
Eng: ACM is used to secure websites and applications with HTTPS.

3.What is an SSL/TLS Certificate?
An SSL/TLS certificate helps establish a secure connection between the user and the application.
It encrypts data transferred between the client and server.
Simple ga gurthupettuko:
SSL/TLS certificate ante user and server madhya data secure ga transfer cheyyadaniki use chestham.
Eng: An SSL/TLS certificate helps secure data between the client and server.

4.How do you get a certificate using ACM?
We can request a certificate in ACM for our domain name.
AWS can validate that we control the domain, commonly using DNS validation or email validation.
Simple ga gurthupettuko:
Domain ki certificate request chesi, domain ownership verify chestham.
Eng: We request a certificate and validate ownership of the domain.

5.What is DNS Validation in ACM?
DNS validation verifies domain ownership by adding a specific CNAME record to the domain's DNS configuration.
Once the record is verified, ACM can issue the certificate.
Simple ga gurthupettuko:
DNS Validation ante ACM ichina CNAME record ni DNS lo add chesi domain ownership prove cheyyadam.
Eng: DNS validation verifies domain ownership using a DNS record.

6.What is Email Validation in ACM?
Email validation verifies domain ownership by sending validation emails to approved domain contacts.
The certificate is issued after the validation request is approved.
Simple ga gurthupettuko:
Email Validation ante domain owner ki email pampinchi ownership verify cheyyadam.
Eng: Email validation verifies domain ownership through email approval.

7.What is ACM Private CA?
ACM Private CA is used to create and manage private certificates for internal applications and resources.
It is useful when certificates are needed inside an organization's private environment.
Simple ga gurthupettuko:
Private CA ante internal applications kosam private certificates create and manage cheyyadaniki use chestham.
Eng: ACM Private CA is used to create and manage private certificates for internal resources.

8.Does ACM automatically renew certificates?
Yes, ACM can automatically renew eligible certificates that are in use with supported AWS services.
This helps avoid certificate expiration and related application downtime.
Simple ga gurthupettuko:
ACM certificate ni eligible AWS services tho use chesthe automatic ga renew cheyyagaladu.
Eng: ACM can automatically renew eligible certificates used with supported AWS services.

9.Where can we use an ACM certificate?
ACM certificates can be used with supported AWS services such as Application Load Balancer and CloudFront.
The certificate allows these services to provide secure HTTPS connections.
Simple ga gurthupettuko:
ACM certificate ni ALB, CloudFront lanti AWS services tho HTTPS kosam use chestham.
Eng: ACM certificates can be used with services such as ALB and CloudFront.

10.How do you use ACM with an Application Load Balancer?
I would request or import a certificate in ACM and validate the domain.
Then I would configure the certificate on the ALB HTTPS listener so that users can securely access the application using HTTPS.
Simple ga gurthupettuko:
ACM Certificate → ALB HTTPS Listener → Secure HTTPS Application.
Eng: I would attach the ACM certificate to the ALB HTTPS listener.

11.How do you use ACM with CloudFront?
I would create or import the required certificate in ACM and configure it for the CloudFront distribution.
This allows users to access the application securely using HTTPS.
Simple ga gurthupettuko:
ACM Certificate → CloudFront → HTTPS.
Eng: An ACM certificate can be configured with CloudFront to provide HTTPS.

12.What is the difference between ACM Public Certificate and Private Certificate?
A public certificate is generally used to secure publicly accessible websites and applications.
A private certificate is used for internal applications and private communication within an organization.
Simple ga gurthupettuko:
Public Certificate = Public website, Private Certificate = Internal application.
Eng: Public certificates secure public applications, while private certificates are used for internal resources.

13.What happens if an SSL/TLS certificate expires?
If the certificate expires, users may receive security warnings and HTTPS connections can be affected.
To avoid this, certificate renewal should be properly managed.
Simple ga gurthupettuko:
Certificate expire ayite HTTPS problem and browser security warning ravachu.
Eng: An expired certificate can cause HTTPS problems and security warnings.

14.What is the most important thing to remember about ACM?
ACM is mainly used to manage SSL/TLS certificates for HTTPS.
The important concepts are certificate request, domain validation, automatic renewal, public certificates, private certificates, and integration with services like ALB and CloudFront.
Simple ga gurthupettuko:
ACM = SSL/TLS Certificate + HTTPS + Validation + Renewal.
Eng: ACM manages SSL/TLS certificates used to secure applications with HTTPS.
