A Day In Life Of DevOps Engineer | DevOps Engineer Daily Tasks | DevOps Engineer

//

my day-to-day tasks or daily routine as a DevOps engineer.
Starting with the morning, which is 9:30. I login at around 9:30, and the first thing I do is check my Outlook for emails. If there's any urgent email, I address it; otherwise, I just check for missed emails. After that, I check Microsoft Teams for any missed messages.
Next, I go to Jira. If you don't know, Jira is a platform used to create tickets. In corporate, whether DevOps or development, all work is tracked via tickets. A ticket is generated with a description of the task, and I assign it to myself so my manager and team can see I am working on it. I also check if there are any new tickets that I need to work on.
Since some tickets may span multiple days, I continue pending tasks and check for new tickets if any. This is part of my morning routine: checking emails, Teams, and Jira tickets.
Secondly, we have a daily standup meeting, known as DSTM (Daily Standup Meeting). All team members give updates on tasks they are working on. It usually lasts 15–20 minutes. You can also mention if you need help so the manager can assign someone else to assist you.

Since we have multiple projects deployed in different infrastructure environments, I monitor the infrastructure using Grafana. I check dashboards for any issues and either fix them myself or consult a senior if needed.
CICD pipelines are an essential part of my work. We update or modify existing pipelines rather than creating new ones daily. If a new requirement arises, like adding a trivy stage for Docker scanning, we update pipelines in lower environments first, test them, then seek approval to deploy in production.
Configuration management happens occasionally. Using Ansible, we update server configurations as per requests from managers or clients. The changes are tested in lower environments first, then approved before deploying to production.
Infrastructure as Code tasks using Terraform are also occasional. Requests may involve provisioning servers or resources with specific tools installed. We modify scripts if needed, provision resources, and share them with the client or engagement.
Monitoring and logging are done daily using Grafana and Prometheus. We collect and analyze data, check dashboards, and fix any issues identified.

Incident response and troubleshooting involve Jira tickets. Clients raise tickets for issues, we assign them, investigate, and resolve problems. This may include connecting with the client on Teams or calls for clarification.
Documentation is important for projects, especially large ones. We document processes, POCs, or implementations in Confluence or SharePoint for future reference.
Self-learning is encouraged when free time is available. We use this time to learn new DevOps tools, attend training, or explore concepts useful for work.
Timesheets are maintained daily to log work hours and tasks. Typically, nine hours are logged, divided among tickets, self-learning, and other tasks.
